The Symbol Table implements a list of Hash Tables, which is used for both identifiers and constants. The Hash Table is a simple hash table with linked list collision resolution. Additionally, the Cell class is implemented to act as a Pair class.

The Symbol Table has the current methods:

put (String key, Object value) {} - acts as the 'add' function by calculating the index using the hash function and inserting it in the correct table using the put method from the Hash Table implemented

 $hash(String\ key)\ \{\}$  - simple hash function which gets the length of the key and maps it to the size of the Symbol Table

The Hash Table has the current methods:

 $\operatorname{put}(K \text{ key}, V \text{ value})$   $\{\}$  - inserts a key-value pair into the hash table, updating the value if the key already exists.  $\operatorname{get}(K \text{ key})$   $\{\}$  - retrieves the value associated with the given key from the hash table, or returns null if the key is not found.  $\operatorname{keys}()$   $\{\}$  - returns an iterable collection of all the keys stored in the hash table.

 $\label{eq:cell_key} \begin{tabular}{ll} $\operatorname{Cell}(K\ key,\ V\ value)\ \{\}$ - initializes\ a\ cell\ with\ a\ key-value\ pair.\ getKey()\ \{\}$ - retrieves\ the\ key\ associated\ with\ the\ cell.\ getValue()\ \{\}$ - retrieves\ the\ value\ associated\ with\ the\ cell.\ setValue(V\ value)\ \{\}$ - updates\ the\ value\ of\ the\ cell\ with\ the\ provided\ value. \end{tabular}$
